REMOVABILITY OF HÖLDER GRAPHS FOR CONTINUOUS SOBOLEV FUNCTIONS

NICOLAE TECU

Abstract. We characterize the removability of Hölder-α graphs with respect to continuous Sobolev $W^{1,2}$ functions. For $\alpha > 2/3$ these graphs are removable, while for $\alpha < 2/3$ there exist graphs which are not removable.

1. Introduction

In this paper we characterize the removability of Hölder graphs with respect to continuous Sobolev functions. The problem of finding necessary and sufficient metric conditions for removability has been studied in previously, most of the time in conjunction with the closely related removability of sets for quasiconformal mappings. In this paper we address the first problem, while making reference to the second one. However, as one will see, the characterization we provide is not yet complete for the class of quasiconformal mappings.

The setting of all the theorems is $\mathbb{R}^2$. Ω is an open set. In the following $W^{1,p}(\Omega)$ will denote the functions in $L^p(\Omega)$ whose distributional partial derivatives are also functions in $L^p(\Omega)$. This means that $u \in W^{1,p}(\Omega)$ if $u \in L^p(\Omega)$ and there are functions $\partial_j u \in L^p(\Omega), j = 1, 2$ such that

$$\int_\Omega u \partial_j \psi dx = - \int_\Omega \psi \partial_j u dx \tag{1}$$

for all test functions $\psi \in C_0^\infty(\Omega)$ and all $1 \leq j \leq n$.

Definition 1. A compact set K is called $W^{1,p}$-removable for continuous functions in $\mathbb{R}^2$, if any function, continuous in $\mathbb{R}^2$ and in $W^{1,p}(\mathbb{R}^2 \setminus K)$ belongs to $W^{1,p}(\mathbb{R}^2)$.

A function $f : \Omega \to \tilde{\Omega}$ is a quasiconformal mapping if f is a homeomorphism, it is absolutely continuous on almost every line parallel to the coordinate axes (ACL), differentiable almost everywhere and $\max_\alpha \partial_\alpha f(x) \leq C \min_\alpha \partial_\alpha f(x)$ holds almost everywhere. The min and max are over directions α.

Date: June 2010.

Definition 2. A compact set $K \subset U$ is quasiconformally removable in $\mathbb{R}^2$, if any homeomorphism of $\mathbb{R}^2$ which is quasiconformal on $\mathbb{R}^2 \setminus K$ is quasiconformal on $\mathbb{R}^2$.

A quick look over the definitions reveals that removability is about the absolute continuity on almost every line and that if a set is $W^{1,2}$-removable for continuous functions then it is also removable for quasiconformal mappings. It is not known whether the converse holds also. Obviously, a set which is not removable for quasiconformal mappings will also be non-removable for continuous $W^{1,2}$ functions.

The quasiconformal removability problem has been extensively studied. F. Gehring proved that any set K of σ-finite length is quasiconformally removable ([4]). It is not difficult to see that any set K of positive area is non-removable. In terms of Hausdorff measure this is the most one can say.

Some of the most significant results have been proven by P. W. Jones and S. Smirnov ([5]) which give sufficient geometric conditions for continuous Sobolev removability. These have been improved by P. Koskela and T. Nieminen in [10]. On the non-removability side, R. Kaufman proved that there are non-removable graphs ([6]) and in a further paper on the topic he showed that for each $\alpha < 1/2$ there is a non-quasiconformally removable Hölder α graph ([7]).

By a *Hölder α graph* we mean the graph of a function $f : [0,1] \to \mathbb{R}$ which satisfies the condition $|f(x)-f(y)| \leq C|x-y|^\alpha$ for all $x, y \in [0,1]$. More generally, by a *Hölder h graph* we mean the graph of a function $f : [0,1] \to \mathbb{R}$ which satisfies the condition $|f(x) - f(y)| \leq h(|x-y|)$ for all $x, y \in [0,1]$, where $h : \mathbb{R}_+ \to \mathbb{R}_+$ is a homeomorphism with $h(0) = 0$. Other aspects of the two problems have been studied by P. Koskela ([9]), R. Kaufman and J-M. Wu ([8]), J-M. Wu ([12]), C. Bishop ([3]) (the list is not exhaustive).

In this paper we prove the following theorems.

Theorem 3. *Let $p > 1, p'$ it's conjugate. The graph of a Hoelder h function is removable for continuous Sobolev $W^{1,p}$ functions if the following condition holds:*

$$\int_0^1 \left(\frac{t}{h^{-1}(t)} \right)^{p'} dt < \infty \tag{2}$$

In particular the condition $\alpha > \frac{p}{2p-1}$ is sufficient for continuous Sobolev $W^{1,p}$ removability. For $p = 2$ we get $\alpha > 2/3$ as sufficient condition (hence also for quasiconformal mappings).

Theorem 4. *Let $p > 1$. Then for each $\alpha < \frac{p}{2p-1}$ there is a Hölder α graph Γ which is not removable for continuous $W^{1,p}$ functions. In particular if $p = 2$ we get $\alpha < 2/3$.*

We do not know what happens for $\alpha = \frac{p}{2p-1}$.

Theorem 5. *For each $\alpha < 1/2$ there is a graph which is non removable for quasiconformal mappings.*

We have not been able to construct a quasiconformally non removable graph for $\alpha \in [1/2, 2/3)$.

Theorem 5 has already been proven by R. Kaufman in [7]. For a comparison of the two proofs and their limitations see the paragraphs after the proof of theorem 5.

For the sake of completeness we give a theorem of Peter W. Jones (personal communication) which shows that for any Sobolev (or quasiconformally) non-removable graph Γ for $\alpha > 1/2$ any interesting function F must satisfy $|\nabla F| \to \infty$ as $(x, y) \to \Gamma$.

Theorem 6. *If F is a function which is ACL off a Hölder α graph Γ, $\alpha > 1/2$,and satisfies $|\nabla F| \leq 1$, then F is globally ACL.*

In the following section we prove the sufficiency result. The last section is dedicated to the non-removability results and to theorem 6.

AcknowledgmentsI would like to thank my advisor, Peter W. Jones, for proposing this problem and for the discussions about it.

2. Proof of sufficiency

In this section we prove Theorem 3. We do this by applying a result of Jones and Smirnov ([5]).

Consider a simply connected domain Ω with a marked point z_0 and it's Whitney decomposition $\{Q\}$. We denote by $Sh(Q)$ the shadow of the square Q through the family of hyperbolic geodesics starting at z_0 and accumulating on the boundary of Ω. In other words, $Sh(Q)$ is the set of accumulation points on $\partial\Omega$ of hyperbolic geodesics that start at z_0 and pass through Q. We denote by $s(Q)$ the euclidean diameter of $Sh(Q)$ and by $l(Q)$ the side length of the square Q. In this section and the next we will use $\approx$ and $\lesssim$ for equality and inequality respectively up to *universal* constants. We will keep track of constants important for the computation separately.

Following [5] we have the following theorem:

Theorem 7. *If for some $p > 1$ a simply connected domain $\Omega \subset \mathbb{R}^2$ satisfies*

$$\sum_Q \left(\frac{s(Q)}{l(Q)}\right)^{p'} l(Q)^2 < \infty \tag{3}$$

then $\partial\Omega$ is removable for continuous Sobolev $W^{1,p}$ functions ($1/p + 1/p' = 1$).

Remark 1. The sum is over the Whitney squares which are at some finite (euclidian) distance to the boundary. The precise distance is not important.

Proof of theorem 3. We consider a Hölder h graph Γ_f and the Whitney decomposition $\{Q\}$ of the complement of the graph. For each $n \in \mathbb{Z}, n \geq 0$ let S_n denote the collection of Whitney squares Q which are at height $\approx 2^{-n}$ above or below the graph Γ_f. Let LR be the collection of squares which are to the left or right of the graph (the projection of any of these squares on the x-axis does not intersect $[0,1]$).

We then have trivially

$$\sum_{Q \in LR} \left(\frac{s(Q)}{l(Q)}\right)^{p'} l(Q)^2 < \infty$$

and need only estimate the rest of the sum:

$$\sum_{Q \notin LR} \left(\frac{s(Q)}{l(Q)}\right)^{p'} l(Q)^2 = \sum_n \sum_{S_n} \left(\frac{s(Q)}{l(Q)}\right)^{p'} l(Q)^2$$

For each of the squares in S_n the following properties hold:

(a) $l(Q) \approx h^{-1}(2^{-n})$
(b) $s(Q) \approx 2^{-n}$

Between height 2^{-n} and 2^{-n+1} there are at most $\approx 2^{-n}/h^{-1}(2^{-n})$ such squares vertically and at most $\approx 1/h^{-1}(2^{-n})$ horizontally.

All these imply

$$\begin{aligned}
\sum_n \sum_{S_n} \left(\frac{s(Q)}{l(Q)}\right)^{p'} l(Q)^2 &\lesssim \sum_n \left(\frac{2^{-n}}{h^{-1}(2^{-n})}\right)^{p'} \left(h^{-1}(2^{-n})\right)^2 \frac{2^{-n}}{(h^{-1}(2^{-n}))^2} \\
&\lesssim \sum_n \left(\frac{2^{-n}}{h^{-1}(2^{-n})}\right)^{p'} 2^{-n} \\
&\lesssim \int_0^1 \left(\frac{t}{h^{-1}(t)}\right)^{p'} dt < \infty
\end{aligned}$$

By theorem 7 we obtain the desired conclusion. □

3. Examples of non-removable graphs

In this section we construct non-removable graphs. We will follow the philosophy of [6]. Compare also with [7].

Proof of theorem 4. We construct a map $u : \mathbb{R}^2 \to \mathbb{R}$ which has the following properties.

(a) it is not identically 0 and it nonnegative
(b) it is continuous
(c) it has partial derivatives almost everywhere and $\frac{\partial u}{\partial x} = 0$ a.e.(off a graph Γ).
(d) it is absolutely continuous on almost every line off Γ, but not globally ACL.
(e) $\nabla u \in L^p$ and $\alpha < \frac{p}{2p-1}$.

The function u above will be the limit of a sequence of functions u_n, each of which has support in $[0,1]^2$, is continuous and is differentiable almost everywhere. It will be given by $u_n(x,y) = \int_0^x A_n(t,y)dt$ for some function A_n.

Together with u_n we also construct a sequence of sets $\{\Gamma_n\}$ with $\cap_n \Gamma_n = \Gamma$. The function A_n above will be supported on Γ_n.

The first step of the procedure is to consider $A_1 : [0,1]^2 \to \mathbb{R}$ which is constant in the x-variable and $A_1(x,0) = A_1(x,1) = 0, \forall x \in [0,1]$. We normalize it to have a maximum 1. Pick two large even numbers M and N (how we pick these will become clear later).

Assume we are now at level n. The function A_n is supported on a finite collection of rectangles of sides $l_n, \tilde{l}_n$ respectively. Γ_n is the union of these rectangles. Inside each rectangle, A_n is constant as a function of the x-variable. Consider one of these rectangles, R.

We divide the y side of R in N pieces and the x side in $2(N-1)M$ pieces. What we get is a collection of small rectangles. In this mesh we mark as black *some* rectangles of sides $l_{n+1} = \frac{l_n}{2(N-1)M}$ and $\tilde{l}_{n+1} = \frac{2\tilde{l}_n}{N}$. Each of these black rectangles will be made of two small rectangles (basically two small ones, one on top of the other). On each column there will be only one black rectangle. Every second column will have no black rectangle in it. Finally, the black rectangles will be placed in the pattern $\Lambda\Lambda\ldots\Lambda$ (see Figure).

If we denote by I_i the projections on the y-axis of the black rectangles we should have $\cup_i I_i =$ the whole y-side of R. In addition $I_i \cap I_{i+1} \neq \emptyset$.

The finite collection $\{I_i\}_{1,N-1}$ is a cover of the y-side of R so we can find a partition of unity ϕ_i subordinated to this cover such that $\sum_i \phi_i(y) = 1$ (this is easy, everything is finite). In fact at most two functions will be non zero for any y.

Now define A_{n+1} to be zero whenever A_n is zero. Set $A_{n+1}(x, y) = 0$ for (x, y) outside of the black rectangles. In each black rectangle the function A_{n+1} is constant as a function of x. We define it such that:

$$A_{n+1}(x,y)l_{n+1}M = \phi_{n+1,i}(y)A_n(x,y)l_n \tag{4}$$

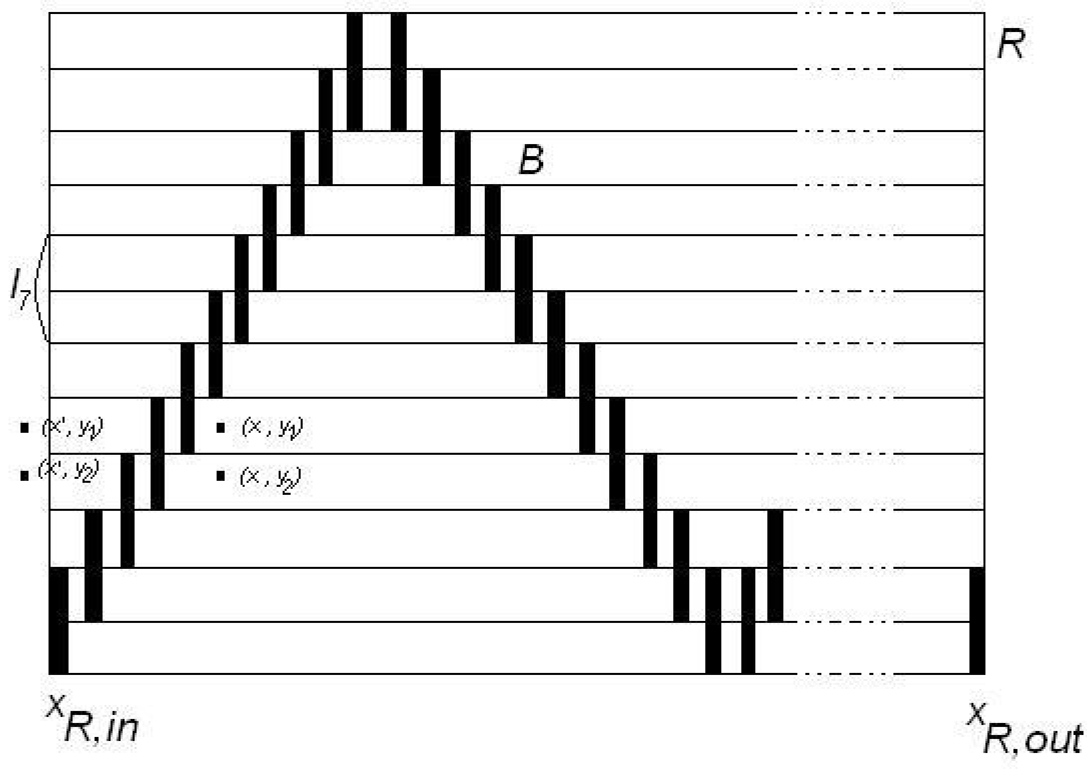
if (x, y) is in a black rectangle with projection I_i on the y-axis. This will ensure that A_{n+1} is supported on the black rectangles.

One can think of u_{n+1} as describing a measure on each line. In this view A_{n+1} is essentially the 'mass' density of u_{n+1}. Condition (4) ensures that the mass on each line is preserved when going from level n to $n + 1$. More rigorously, for each y:

$$\begin{aligned} \int_{x_{R,in}}^{x_{R,out}} A_n(t,y)dt &= \int_{x_{R,in}}^{x_{R,out}} A_{n+1}(t,y)dt \qquad (5) \\ &= \sum_{B-\text{black rect}} \int_{x_{B,in}}^{x_{B,out}} A_{n+1}(t,y)dt \qquad (6) \end{aligned}$$

Here $x_{R,in}, x_{R,out}$ are the first and the last x coordinates for which (x, y) is in rectangle R.

Γ_{n+1} is defined as the union of all black rectangles from all rectangles $R \subset \Gamma_n$.



Since $u_n(x,y) = \int_0^x A_n(t,y)dt$ we have $\frac{\partial u_n}{\partial x} = 0$ outside Γ_n. In addition, $u_{n+i}(x,y) = u_n(x,y)$ for all $(x,y) \notin \Gamma_n, \forall i \geq 1$.

We also have the relation:

$$|u_{n+1}(x,y) - u_n(x,y)| = |\int_0^x A_{n+1}(t,y) - A_n(t,y)dt| \tag{7}$$

Because the function u_{n+1} is no different than u_n outside Γ_n, the supremum of these quantities is reached when $x \in [x_{B,in}, x_{B,out}]$, where $B \subset \Gamma_n$ is the black rectangle for which $(x,y) \in B$. We then have:

$$|u_{n+1}(x,y) - u_n(x,y)| \lesssim \frac{A_n(x,y)l_n}{M} \tag{8}$$

By the defining relation of A_n , (4), we get:

$$\sup_{x,y} A_n(x,y) \quad \lesssim \quad \frac{1}{M^n l_n} \tag{9}$$

and

$$\frac{\partial A_{n+1}(x,y)}{\partial y} l_{n+1} M = \frac{\partial \phi_{n+1,i}(y)}{\partial y} A_n(x,y) l_n + \phi_{n+1,i}(y) \frac{\partial A_n(x,y)}{\partial y} l_n$$

We keep in mind that $\sup|\phi_{n+1,i}| \leq 1$ and its support is of length $\tilde{l}_{n+1}$ and get $\sup|\partial\phi_{n+1,i}/\partial y| \lesssim \frac{1}{\tilde{l}_{n+1}}$. Then we compute recursively and get:

$$\sup_{x,y} |\frac{\partial A_n(x,y)}{\partial y}| \lesssim \frac{1}{M^n l_n \tilde{l}_n} \tag{10}$$

We may thus conclude:

$$|u_{n+1}(x,y) - u_n(x,y)| \lesssim \frac{1}{M^{n+1}} \tag{11}$$

Since $M > 1$ $u_n \to u$ uniformly. u will thus be continuous. In addition, $u(x,y) = u_n(x,y)$ for $(x,y) \notin \Gamma_n$ so u satisfies all the properties we set out to fulfill, except the last one.

We will now estimate $b_{n+1} = \sup|\frac{\partial u_{n+1}(x,y)}{\partial y}|$ for $(x,y) \in \Gamma_n \setminus \Gamma_{n+1}$. Consider $(x,y_1),(x,y_2)$ which satisfy these conditions and pick x' such that $(x',y_1),(x',y_2)$ lie just outside and to the left of the black rectangle of level n in which we picked $(x, y_1), (x, y_2)$. Then

$$\begin{aligned}
|u_{n+1}(x,y_1) - u_{n+1}(x,y_2)| &\leq |u_{n+1}(x',y_1) - u_{n+1}(x',y_2)| + \\
&+ |u_{n+1}(x,y_1) - u_{n+1}(x',y_1) + u_{n+1}(x',y_2) - u_{n+1}(x,y_2)| \\
&\leq |u_n(x',y_1) - u_n(x',y_2)| + \\
&+ |\int_{x'}^{x} A_{n+1}(t,y_1)dt - \int_{x'}^{x} A_{n+1}(t,y_2)dt| \\
&\leq b_n|y_2 - y_1| + |\int_{x'}^{x} A_{n+1}(t,y_1) - A_{n+1}(t,y_2)dt| \\
&\leq b_n|y_2 - y_1| + \int_{x'}^{x} \sup|\frac{\partial A_{n+1}(t,y)}{\partial y}||y_2 - y_1|dt \\
&\leq b_n|y_2 - y_1| + \frac{C|y_2 - y_1|Ml_{n+1}}{M^{n+1}l_{n+1}\tilde{l}_{n+1}} \\
&\leq \left(b_n + \frac{C}{M^n\tilde{l}_{n+1}}\right)|y_2 - y_1| \qquad (12)
\end{aligned}$$

We may now write

$$b_{n+1} \leq b_n + \frac{C}{M^n\tilde{l}_{n+1}}$$

C above denotes a universal constant! Now, we have $l_n < \frac{1}{N^n M^n}, \tilde{l}_n = \frac{2^n}{N^n}$ so we have

$$b_{n+1} \lesssim \sum_{i=2}^{n+1} \frac{N^i}{2^i M^{i-1}} \lesssim N \sum_{2}^{n+1} \frac{N^{i-1}}{M^{i-1}} \lesssim \frac{N}{N/M - 1}\frac{N^{n+1}}{M^{n+1}}$$

if $N > M$. In case $N \leq M$ we have $b_{n+1} \lesssim N$.

We define $\Gamma = \cap_n \Gamma_n$. It is easy to see this is the graph of a function.

Keeping in mind that $|\frac{\partial u}{\partial y}| \leq b_n$ for $(x,y) \in \Gamma_n \setminus \Gamma_{n-1}$ we can write:

$$\begin{aligned}
\int_{\Gamma^C} |\nabla u|^p dxdy &\lesssim \sum_n M^n N^n l_n \tilde{l}_n b_n^p \lesssim C(N,M) \sum_n \frac{2^n}{N^n}\frac{N^{np}}{M^{np}} \\
&\lesssim C(N,M) \sum_n \left(\frac{2N^{p-1}}{M^p}\right)^n \qquad (13)
\end{aligned}$$

So the L^p integral of ∇u is going to be finite if and only if

$$\frac{2N^{p-1}}{M^p} < 1 \qquad (14)$$

The constant $C(N,M)$ is finite for all N, M. If $N \leq M$ the integral is trivially finite. In this case we actually obtain a Lipschitz function u. We will come back to this later.

We have up to this point constructed a function u which satisfies all the properties we wanted. This function is ACL on Γ^C, where Γ is the graph of a function. To ensure this is a Hölder α graph we should have:

$$\tilde{l}_n \leq \left(\frac{l_n}{M}\right)^{\alpha} \forall n > 0 \tag{15}$$

We write $M = 2^a, N = 2^b$. M is actually a constant (large, but nevertheless a constant) so we can disregard it above. Conditions (14) and (15) become:

$$\begin{aligned} b(p-1)+1 &< ap \\ 1+\alpha+a\alpha &\leq b(1-\alpha) \end{aligned}$$

The second relation becomes:

$$\begin{aligned} \alpha(1+a+b) &\leq b-1 \Rightarrow \alpha \leq \frac{b-1}{1+a+b} < \frac{b-1}{1+b+\frac{b(p-1)+1}{p}} \\ &< \frac{p(b-1)}{p+b(2p-1)+1} \to \frac{p}{2p-1} \text{ as } b \to \infty. \end{aligned}$$

We thus see that if we pick a, b large enough Γ will be a Hölder α graph. And this is possible for all $\alpha < \frac{p}{2p-1}$. □

Proof of theorem 5. We have $p = 2$. For $\alpha < 1/2$ one can take $N < M$ above which implies $|\nabla u| < C$. Consider the function $F : \mathbb{C} \to \mathbb{C}, F(z) = z + u(x,y)$. This function maps horizontal lines to horizontal lines and on each one of them the function is strictly increasing. Hence it is a homeomorphism. Since $|\nabla u| < C$ the Beltrami differential has norm $< k < 1$ and so F is quasiconformal off Γ. On the other hand F is not globally ACL (because u isn't), hence not globally quasiconformal. □

We have not been able to construct a quasiconformally non removable graph for $\alpha \in [1/2, 2/3)$. The trouble is that one is forced to pick $N \geq M$ and that leads to a function u with Beltrami coefficient μ_F which satisfies $||\mu_F||_\infty = 1$. We hoped we could solve the Beltrami equation for μ_F and correct F, but our attempts were not successful, neither using the generalization to the Measurable Riemann Mapping theorem for exponential distortion, nor using Lehto's theorem ([1], chapter 20). In our model it is possible to make F a homeomorphism, but very difficult to make it quasiconformal off the graph.

In his proof, R. Kaufman defined a function $F = Az + \int \frac{1}{z-w} d\mu(w)$ for some constant A and measure μ supported on a graph. The gradient of the Cauchy transform turned out to be bounded off Γ which meant that for large A F was a homeomorphism. For $\alpha \geq 1/2$ any interesting function can't be Lipschitz anymore (see below) so the Cauchy transform can't be Lipschitz which in turn means that most likely F will not be a homeomorphism.

Proof of theorem 6. It was proven by A. S. Besicovitch and H. D. Ursell ([2]) that

$$Hdim(\Gamma) \leq 2 - \alpha$$

An easy consequence is that for almost every horizontal line l:

$$Hdim(\Gamma \cap l) \leq 1 - \alpha \tag{16}$$

(See e.g. [11], theorem 7.7) Consider one such line l and on which $F|_{\Gamma^C}$ is absolutely continuous. Let $\epsilon > 0$. We want δ such that if $\sum_i |x_i - y_i| < \delta$ then $\sum_i |F(x_i) - F(y_i)| < \epsilon$. We have two types of intervals (x_i, y_i) (on line l): some which don't contain any point of the graph Γ (we call them 'good') and some which do (we call them 'bad').

Without loss of generality we may consider only the case when the bad intervals are an open cover of $\Gamma \cap l$. Since $\alpha > 1/2$ there exists $\tau > 0$ such that $2\alpha > 1 + \tau$. By (16) we may pick an open cover $\{(\tilde{x}_j, \tilde{y}_j)\}$ of $\Gamma \cap l$ such that $|\tilde{x}_j - \tilde{y}_j| \leq \inf_i |x_i - y_i|$ (this is actually a minimum) and such that

$$\sum_j |\tilde{x}_j - \tilde{y}_j|^{1-\alpha+\tau} < 1$$

We also must have for each $j : (\tilde{x}_j, \tilde{y}_j) \subset (x_i, y_i)$ for some i and

$$\sum_j |\tilde{x}_j - \tilde{y}_j| \leq \sum_{bad} |x_i - y_i| < \delta$$

Finally, we also have that the intervals composing $(x_i, y_i) \setminus \cup_j (\tilde{x}_j, \tilde{y}_j)$ are actually in the complement of $l \cap \Gamma$ so we can lump them with the good intervals. We can redefine the "bad" collection of intervals to be $\{(\tilde{x}_j, \tilde{y}_j)\}$. The collection of all the intervals "good" and "bad" is a refinement of the one we started with.

Since Γ is a Hölder α graph and $|\nabla F| \leq 1$ we get $|F(\tilde{x}_j) - F(\tilde{y}_j)| \leq |\tilde{x}_j - \tilde{y}_j|^\alpha$. By the definition of τ we have $p = \frac{\alpha - \tau}{1-\alpha} > 1$. Take q to be its conjugate and set $\alpha_1 = \frac{1-\alpha+\tau}{p}, \alpha_2 = \frac{1}{q}$. Then $\alpha = \alpha_1 + \alpha_2$. We may now write:

$$\begin{aligned} \sum_j |F(\tilde{x}_j) - F(\tilde{y}_j)| &\leq \sum_j |\tilde{x}_j - \tilde{y}_j|^\alpha \leq \left(\sum_j |\tilde{x}_j - \tilde{y}_j|^{p\alpha_1} \right)^{1/p} \left(\sum_j |\tilde{x}_j - \tilde{y}_j|^{q\alpha_2} \right)^{1/q} \\ &< \left(\sum_j |\tilde{x}_j - \tilde{y}_j|^{1-\alpha+\tau} \right)^{1/p} \left(\sum_j |\tilde{x}_j - \tilde{y}_j| \right)^{1/q} \leq \delta^{1/q} \end{aligned} \tag{17}$$

Since the good intervals are in the complement of Γ we use $|\nabla F| \leq 1$ to get

$$\sum_{good} |F(x_i) - F(y_i)| \leq \sum_{good} |x_i - y_i| < \delta$$

We are done once we pick δ small enough. $\square$
